1. The purpose of converting raw audio into spectrogram/MFCC style is because the raw waveform doesn't give us as much useful information. Spectrogram/MFCC-style helps us see the different frequencies which we need to be able to distinguish the words we are saying.
2. Representative dataset is for the range of input values we want the model to see. It's important because model accuracy can be affected if the calibration isn't done correctly after quantization.
3. Audio_processor.get_data() gets the audio features and returns data and labels based on the partition offset and batch size.
4. G_model is the array that contains the compiled TensorFlow Lite model, g_model_len is the number of bytes in the array. They need to be copied correctly because that information is what Arduino uses to run the model. If the array is wrong, it may fail to compile, compile incorrectly, or fail to upload.
5.
